The compounds of this invention can be prepared by various processes, for example, by the following reaction schemes.

Reaction Scheme-1

wherein  $R^3$  is as defined above.

The compounds (1-a) of this invention can be prepared by reacting a compound (2) with an alkyl orthoformate (e.g. methyl orthoformate, ethyl orthoformate, etc.). The reaction can be carried out in a solvent which does not affect on the reaction, but since the alkyl orthoformate can also act as a solvent, use of a specific solvent is not necessarily essential. The reaction is usually carried out by using about 15 moles of the alkyl orthoformate per 1 mole of the compound (2) at a temperature of 80 to 120°C for about 2 to 15 hours.

Reaction Scheme-2

wherein  $R^3$  is as defined above and  $R^6$  is a lower alkyl.

The compounds (1-b) of this invention can be

prepared by subjecting the compound (3) to a cyclization reaction with a basic compound such as an alkali metal hydroxide (e.g. sodium hydroxide, potassium hydroxide, etc.) or an alkaline earth metal hydroxide (e.g. calcium hydroxide, etc.). The reaction can be carried out in a solvent which does not affect on the reaction, for example, a lower alcohol (e.g. methanol, ethanol, etc.). The reaction is usually carried out by using about 4 moles of the basic compound per 1 mole of the compound (3) at a temperature of -10 to 5°C for about 5 to 40 hours.

Reaction Scheme-3

wherein  $R^1$  and  $R^3$  are as defined above.

The above process comprises converting the 2-mercapto group of the pyrazolotriazine compound (1-b) into hydroxy group to obtain the compound (1-c). The reaction can be carried out by reacting the compound (1-b) with hydrogen peroxide and an alkali metal hydroxide (e.g. sodium hydroxide, potassium hydroxide, etc.) in a solvent (e.g. water). The reaction is usually carried out by using about 20 moles of hydrogen peroxide per 1 mole of the compound (1-b) and about 2 moles of the alkali metal hydroxide per 1

mole of the compound (1-b) under ice-cooling for about 1 to 3 hours.

Reaction Scheme-4

wherein  $\text{R}^3$  is as defined above,  $\text{R}^1\text{a}$  is a lower alkanoyl, and  $\text{R}^2\text{a}$  is hydrogen atom, hydroxy, or mercapto.

The above process comprises acylating the 4-hydroxy group of the compound (1-d) to obtain the compound (1-e). The reaction can be carried out by a conventional acylating reaction, for example, an acid halide method, an acid anhydride method, a mixed acid anhydride method, an N,N'-dicyclohexylcarbodiimide method (DCC method), and the like, particularly preferably by an acid anhydride method or an acid halide method.

The acid anhydride method can be carried out by reacting the compound (1-d) with an acid anhydride in a suitable solvent. The acid anhydride includes an anhydride of an acid corresponding to the acyl group to be introduced into the 4-hydroxy group of the compound (1-d). Suitable examples of the acid anhydride are acetic anhydride, propionic anhydride, butyric anhydride, etc. These acid anhydrides are used in an amount of at least 1 mole,

preferably about 1 to 3 moles, per 1 mole of the compound (1-d). The solvent includes various inert solvents, such as pyridine, halogenated hydrocarbons (e.g. chloroform, dichloromethane, etc.), ethers (dioxane, tetrahydrofuran (THF), etc.), aromatic hydrocarbons (e.g. benzene, toluene, etc.), N,N-dimethylformamide (DMF), dimethylsulfoxide (DMSO), acetonitrile, and the like. The reaction is usually carried out at a temperature from about  $-30^{\circ}\text{C}$  to  $100^{\circ}\text{C}$ , preferably from room temperature to  $80^{\circ}\text{C}$ , for about 20 minutes to 20 hours. Besides, the reaction proceeds preferably in the presence of a basic compound. The basic compound includes, for example, organic basic compounds such as tertiary amines (e.g. pyridine, triethylamine, N,N-dimethylaniline, etc.), and inorganic basic compounds such as sodium hydrogen carbonate, potassium carbonate, sodium acetate, and the like.

The acid halide method is carried out by reacting the compound (1-d) with an acid halide corresponding to the acyl group to be introduced (e.g. acid chloride, acid bromide, etc.) in the presence of a basic compound in a suitable solvent. The solvent and basic compound include the same solvents and basic compounds as mentioned as to the above acid anhydride method. The reaction is usually carried out at a temperature from  $-30^{\circ}\text{C}$  to  $80^{\circ}\text{C}$ , preferably from  $0^{\circ}\text{C}$  to room temperature, for about 5 minutes to 10 hours.

The compounds of this invention can be prepared by the above-mentioned processes of Reaction Schemes-1 to -4, and further, the compounds having a substituent(s) on the phenyl ring or the unsaturated heterocyclic ring having nitrogen or sulfur atom at 8-position of the compounds can also be prepared by introduction of the substituent(s) or exchange of the substituent(s) as mentioned below. In the following explanation, only the substituent(s) to be introduced or exchanged is mentioned, but the compounds may have any various substituents on the phenyl ring or the unsaturated heterocyclic ring as defined in the claims.

#### Exchange Reaction-1

In case of the compound having a lower alkyl group on the phenyl ring, the lower alkyl group can be converted into a carboxy group by oxidizing it with an oxidizing agent such as potassium permanganate, chromic acid, and the like. The exchange reaction can be carried out in a solvent (e.g. water) under ice cooling for about 5 to 24 hours. The oxidizing agent is preferably used in an amount of 1 to 2 moles to 1 mole of the compound having a lower alkyl group.

#### Exchange Reaction-2

In case of the compound having a carboxy group on the phenyl ring, the carboxy group can be converted into a corresponding ester group by a conventional esterification reaction. The exchange reaction can be carried out by reacting the compound having a carboxy group with a lower

alcohol (e.g. methanol, ethanol, etc.) in the presence of a catalyst (e.g. sulfuric acid, hydrogen chloride, etc.) at a boiling point of the solvent for about 24 hours. The lower alcohol is preferably used in an amount of about 100 to 500 moles to 1 mole of the compound having a carboxy group.

#### Exchange Reaction-3

In case of the compound having a phenyl group substituted by a lower alkyl group containing methylene group, the methylene group can be converted into a carbonyl group by a conventional oxidization reaction. The exchange reaction can advantageously be carried out by using an oxidizing agent such as selenium dioxide, chromic acid, and the like in a solvent (e.g. acetic acid, a mixture of acetic acid and water, etc.) at a room temperature for about 10 to 18 hours. The oxidizing agent is used in an amount of about 5 moles to 1 mole of the compound containing methylene group.

#### Exchange Reaction-4

In case of the compound having a lower alkylene-dioxy group (i.e. the carbonyl group being protected with a lower alkylene) on the phenyl ring, the lower alkylene-dioxy group can be converted into a carboxy group by subjecting it to a conventional removal of a protecting group. The exchange reaction can advantageously be carried out by reacting one mole of the compound having a lower alkylene-dioxy group with about 10 moles of a mineral acid (e.g.

hydrochloric acid, sulfuric acid, etc.) in a solvent at a temperature of 40 to 60°C for about 1 to 3 hours. The solvent used in the above exchange reaction includes a mixture of a lower alcohol (e.g. methanol, ethanol, etc.) and water.

#### Exchange Reaction-5

In case of the compound having a phenyl ring or an unsaturated heterocyclic group having nitrogen or sulfur atom as the hetero atom (hereinafter, referred to merely as unsaturated heterocyclic group) of this invention, nitro group can be introduced onto the phenyl ring or the unsaturated heterocyclic group by a conventional nitration reaction. The reaction can advantageously be carried out under the conditions as used in a conventional nitration reaction, for example, by treating with conc. nitric acid, fuming sulfuric acid, or a mixture of conc. nitric acid - conc. sulfuric acid in a solvent (e.g. acetic acid) at a temperature from room temperature to about 60°C for about one hour. In case of introduction of nitro group onto the above unsaturated heterocyclic group, the reaction is preferably carried out at room temperature.

#### Exchange Reaction-6

In case of the compound having a nitro group on the phenyl ring, the nitro group can be converted into an amino group by a conventional catalytic reduction. The exchange reaction can advantageously be carried out, for example, by

subjecting the compound to a hydrogenation with palladium-carbon in a mixed solvent of methanol-water at room temperature for about 14 hours.

#### Exchange Reaction-7

In case of the compound having an alkoxy group having optionally a phenyl substituent on the phenyl ring, the alkoxy group can be converted into a hydroxy group by reacting it with an aluminum halide. The exchange reaction can be carried out by using an aluminum halide (e.g. aluminum chloride, aluminum bromide, etc.) of about 6 moles to 1 mole of the compound having an alkoxy group in a solvent such as an aromatic compound (e.g. nitrobenzene, chlorobenzene, etc.). The reaction is advantageously carried out at a temperature of from room temperature to about 60°C for about 1 to 5 hours.

When the alkoxy group is benzyloxy group, the reaction is preferably carried out at room temperature for about one hour.

#### Exchange Reaction-8

In case of the compound having hydroxy group on the phenyl ring, the hydroxy group can be converted into an acyloxy group by reacting it with a lower fatty acid anhydride or lower fatty acid halide in such a manner as the acylation reaction in the above Reaction Scheme-4. The exchange reaction can be carried out by reacting one mole of the compound having hydroxy group on the phenyl ring with at least one mole, preferably 1.1 to 1.5 mole, of the lower

fatty acid anhydride or lower fatty acid halide. The reaction is advantageously carried out at room temperature for about 45 minutes.

#### Exchange Reaction-9

In case of the compound having a lower alkylthio group on the phenyl ring, the lower alkylthio group can be converted into a lower alkylsulfinyl group by oxidizing it with an oxidizing agent such as periodate, hydrogen peroxide, and the like. The exchange reaction can be carried out by using a periodate (e.g. sodium periodate, potassium periodate, etc.) of about 2 moles to 1 mole of the compound having a lower alkylthio group in a solvent such as a mixture of a lower alcohol (e.g. methanol, ethanol, etc.) with water (40 : 1). The reaction is advantageously carried out at room temperature for about 40 hours. Besides, the reaction can also be carried out under the same conditions as in the above Exchange Reaction-3 except that the above-mentioned solvent is used.

Moreover, in case of the compound having a phenylthio group on the phenyl ring, the phenylthio group can be converted into a phenylsulfinyl group in the same manner as described above.

#### Exchange Reaction-10

In case of the compound having a lower alkylthio group or lower alkylsulfinyl group on the phenyl ring, the lower alkylthio or alkylsulfinyl group can be converted into a lower alkylsulfonyl group by oxidizing it with hydrogen

peroxide. The exchange reaction can be carried out by reacting one mole of the compound having a lower alkylthio or lower alkylsulfinyl group on the phenyl ring with about 30 moles of hydrogen peroxide in a solvent (e.g. acetic acid). The reaction is advantageously carried out at a temperature of about 70 to 80°C for about one hour.

#### Exchange Reaction-11

Introduction of phenylthio group onto an unsaturated heterocyclic group can be done by reacting a compound having an unsaturated heterocyclic group with a halogenothiobenzene. The reaction can be carried out by reacting one mole of the compound having an unsaturated heterocyclic group with about 1.2 mole of a halogenothiobenzene which is prepared by reacting mercaptobenzene and an N-halogenated succinimide (e.g. N-chlorosuccinimide, N-bromosuccinimide, etc.), in an aprotic solvent (e.g. N,N-dimethylformamide, N,N-dimethylacetamide, etc.). The reaction is advantageously carried out at a temperature from 0°C to room temperature for about 2 hours.

#### Exchange Reaction-12

Introduction of the group:  $-\text{SO}_2-\text{N} \begin{smallmatrix} \text{R}^4 \\ \text{R}^5 \end{smallmatrix}$  (wherein  $\text{R}^4$  and  $\text{R}^5$  are as defined above) onto the phenyl ring can be done by introducing sulfonic group onto the phenyl ring by reacting a compound having a phenyl group with a halogenosulfonic acid and subjecting the resultant to a conventional amido bond forming reaction. The halogeno-

sulfonic acid used in the above reaction includes chlorosulfonic acid, bromosulfonic acid, and the like. The above reaction can advantageously be carried out by reacting one mole of a compound having a phenyl group with about 20 to 25 moles of a halogenosulfonic acid at about 80°C for about 1 to 3 hours, by which chlorosulfonyl group is introduced onto the phenyl ring, and then reacting the resultant with an amine of the formula:  $\text{HN} \begin{matrix} \nearrow \text{R}^4 \\ \searrow \text{R}^5 \end{matrix}$  (wherein  $\text{R}^4$  and  $\text{R}^5$  are as defined above) without using a solvent or in the presence of an organic basic compound (e.g. pyridine, triethylamine, etc.) at a temperature of 50 to 100°C for about 2 to 15 hours.

#### Exchange Reaction-13

Introduction of a halogen atom onto the phenyl ring can be done by a conventional halogenation reaction. The halogenation reaction can be done by reacting one mole of a compound having a phenyl group with about 5 moles of a halogen molecule in a solvent such as an aromatic compound (e.g. nitrobenzene, chlorobenzene, bromobenzene, etc.). The reaction is advantageously carried out in the presence or absence of a catalyst (e.g. aluminum chloride, etc.) at a temperature of 50 to 60°C for about 4 hours.

Besides, when a compound having a phenylthio group on the phenyl ring is subjected to the above-mentioned halogenation reaction at room temperature for about 12

hours, the compound having a phenylthio group on the phenyl ring can be converted into a compound having a halogen-substituted phenylthio group on the phenyl ring.

Moreover, when a compound having an unsaturated heterocyclic group is subjected to the above-mentioned halogenation reaction at room temperature for about one hour, a halogen atom can be introduced onto the unsaturated heterocyclic group of the compound having an unsaturated heterocyclic group.

by using about 1.1 to 1.5 mole of the hydrazine compound per 1 mole of the compound (5) at a boiling temperature of the solvent for about 1 to 4 hours.

Reference Example 1

(1) A mixture of 4-chloro-3-nitrobenzoic acid (241.88 g), sodium hydrogen carbonate (100.80 g) and 50 % aqueous methanol (90 ml) is stirred under nitrogen at room temperature, and thereto is added in order thiophenol (128.35 ml) and a solution of sodium hydroxide (49.6 g) in 50 % aqueous methanol (200 ml). After the addition is completed, the mixture is refluxed under nitrogen atmosphere for one hour. After the reaction is completed, the reaction mixture is cooled with ice water and then adjusted to pH 2-3 with conc. hydrochloric acid. The resulting yellow precipitate is separated by filtration and washed with water to give 3-nitro-4-phenylthiobenzoic acid. This product is used in the subsequent reaction without further purification.

(2) To a mixture of the 3-nitro-4-phenylthiobenzoic acid obtained above, iron powder (201.0 g) and 50 % aqueous ethanol (800 ml) is added gradually with stirring a solution of conc. hydrochloric acid (20 ml) in ethanol (40 ml) under reflux. The mixture is refluxed with stirring for 15 hours, and the reaction mixture is cooled. The precipitate is separated by filtration and washed with water. To the precipitate are added sodium hydroxide (50 g) and water (1.95 liter), and the mixture is heated to dissolve them. Insoluble materials are removed by filtration, and the filtrate is adjusted to pH 2-3 with diluted sulfuric acid under ice cooling. The precipitate is separated by filtration, washed with water and dried to give 3-amino-4-phenylthiobenzoic acid (218.28 g).

To the mixture is added a solution of sodium nitrite (36.25 g) in water (80 ml) which is previously ice-cooled over a period of about one hour. The mixture is further stirred at 0-5°C for 30 minutes. To the mixture is added urea (2 g), and the mixture is stirred for 30 minutes to decompose the unreacted nitrous acid. The resulting mixture is gradually added with stirring to a mixture of conc. sulfuric acid (121 ml), anhydrous sodium sulfate (168 g) and

water (112 ml) at 100 - 110°C over a period of one hour and 15 minutes. After the addition, the mixture is stirred at the same temperature for one hour. The reaction mixture is cooled, and the resulting brown granular precipitate is separated by filtration, washed with water, and dried at 50°C overnight. The product is added to a mixture of methanol (1.4 liter) and conc. sulfuric acid (70 ml), and the mixture is refluxed with stirring for 2 hours.

After the reaction is completed, the reaction mixture is concentrated under reduced pressure, and to the residue is added water (1.5 liter), and the mixture is extracted with ethyl acetate (500 ml x 3). The combined extracts are dried over anhydrous sodium sulfate and concentrated under reduced pressure. The residue is extracted with heated hexane (4.2 liter), and the extract is cooled. Preparations of this invention are illustrated below.

### Preparation

Film coated tablets are prepared from the following components.

<u>Components</u>	<u>Amount</u>
4-Hydroxy-8-[4-(4-methylphenylthio)-phenyl]pyrazolo[1,5-a]-1,3,5-triazine	100 g
Avicel (tradename of microcrystalline cellulose, manufactured by Asahi Chemical, Japan)	40 g
Corn starch	30 g
Magnesium stearate	2 g
TC-5 (tradename of hydroxypropyl methylcellulose manufactured by Shinetsh Kagaku Kogyo, Japan)	10 g
Polyethylene glycol 6000	3 g
Castor oil	40 g
Ethanol	40 g

4-Hydroxy-8-[4-(4-methylphenylthio)phenyl]pyrazolo-[1,5-a]-1,3,5-triazine, Avicel, corn starch and magnesium stearate are mixed and kneaded and the mixture is tabletted using a conventional pounder (R 10 mm) for sugar coating. The tablets thus obtained are coated with film coating agent consisting of TC-5, polyethylene glycol 6000, castor oil and ethanol to give film coated tablets.

The pharmacological properties of the compounds were tested as shown in the following Experiments.

#### Experiment 1 (In vitro)

(1) Preparation of xanthine oxidase solution:  
ICR strain mice were decapitated and the small

intestine of each mouse was rapidly perfused with cooled physiological saline solution and removed. The small intestine was homogenized in 4-fold volume of cooled phosphate buffered saline solution (PBS) and then centrifuged at 105,000 g for 60 minutes. The supernatant fluid was dialyzed overnight against PBS. The dialyzed solution thus prepared was stored at  $-20^{\circ}\text{C}$  until used.

(2) Preparation of the solution containing the present compound:

The compound of this invention was dissolved in DMSO (200  $\mu\text{l}$ ) and 2N NaOH (100  $\mu\text{l}$ ), and then PBS was added to prepare a solution (25 ml) containing  $10^{-3}$  M of the compound of this invention. This solution was diluted with PBS to prepare solutions containing the compound in the concentration of  $10^{-4}$ ,  $10^{-5}$ ,  $10^{-6}$ ,  $10^{-7}$ ,  $10^{-8}$ ,  $10^{-9}$ ,  $10^{-10}$ , and  $10^{-11}$  M, respectively.

(3) Method for the measurement:

The assay mixture, consisted of the composition mentioned below, was incubated at  $37^{\circ}\text{C}$  for 5 minutes. The reaction was stopped by heating in boiling water for one minute. Twenty microliters of the supernatant was analyzed by high performance liquid chromatography (HPLC) under the conditions mentioned below.

Composition of solution

Xanthine oxidase solution (diluted in 4-folds with PBS)	200 $\mu$ l
Xanthine (1 mM)	100 $\mu$ l
Solution containing the present compound	200 $\mu$ l
PBS	500 $\mu$ l

Conditions of HPLC

Column: Cosmosil packed column ( $\phi$  4.6 mm x 150 mm, 5C<sub>18</sub>-300)

Eluting solution: 10 mM phosphate buffer (pH 6.0)

Flow rate: 1.0 ml/minute

Detector: UV 292 nm

Sample volume: 20  $\mu$ l

Retention time: 2.4 minutes (uric acid)

(4) Percent inhibition of the compound against xanthine oxidase:

The percent inhibition was calculated by the following equation.

Percent inhibition (%) =

$$\frac{[\text{Amount of uric acid in control solution}] - [\text{Amount of uric acid in the solution treated with the present compound}]}{\text{Amount of uric acid in control solution}^*} \times 100$$

\*) Control solution means a mixture of DMSO and 2N NaOH used for the preparation of the solution containing the present compound.

As to each of the solutions containing the present compound as prepared in the above (2), the percent

inhibition was calculated, and  $IC_{50}$  values were obtained from a plot of the percent inhibition against the log of the concentration of the compound of this invention.

As a positive control, a commercially available xanthine oxidase inhibitor, allopurinol (= 4-hydroxypyrazolo[3,4-d]pyrimidine) was used.

The experimental results are shown in the table hereinafter.

Experiment 2 (In vivo: oral administration)

(1) Animals, method of administration and sampling of serum:

Normal male ICR mice (weighting about 30 g), were provided normal diet and tap water ad libitum. A test compound suspended in 0.5 % CMC-Na was administered orally to the mice (each group: 6 mice) in a dose of 5 mg/kg. Four hours after the administration of the test compound, blood (about 0.6 ml) was collected from the vena cave inferior of mice under ether anesthesia, and the serum was separated from the blood in a usual manner.

(2) Measurement of amount of uric acid in serum:

To the serum (200  $\mu$ l) was added 10 % perchloric acid (100  $\mu$ l), and the mixture was centrifuged. To the supernatant fluid (100  $\mu$ l) was added 0.2 M  $Na_2HPO_4$  (200  $\mu$ l), and the mixture (20  $\mu$ l) was analyzed by HPLC to measure the amount of uric acid. The HPLC was carried out under the following conditions.

Column: Cosmosil packed column ( $\phi$  4.6 mm x 150 mm,  
5C<sub>18</sub>-300)

Eluting solution: 10 mM phosphate buffer (pH 6.0)

Flow rate: 1.0 ml/minute

Detector: UV 292 nm

Sample volume: 20  $\mu$ l

Retention time: 2.4 minutes (uric acid)

(3) Lowering effect of test compound on the level  
of uric acid in serum:

The lowering rate of uric acid in serum was calculated by the following equation.

Lowering rate of uric acid in serum (%) =

$$\frac{[\text{Amount of uric acid in control animal}] - [\text{Amount of uric acid in the animal treated with the present compound}]}{\text{Amount of uric acid in control animal}} \times 100$$

As a positive control, a commercially available xanthine oxidase inhibitor, allopurinol was used.

The experimental results are shown in the table hereinafter.
